Embedded System Design Development Board

A PCB designed to support embedded system laboratory experiments utilizing the 8051 processor and peripherals

If you don't have a resistor, just short across the pads for R2.

An ammeter may be put in series between the two pins of J6 in order to measure the 5V current drawn by the board. If not using a header, just solder a wire between the two pads of J6.

If you have an 8-pin header, put it in positions 1-8, since pin 9 (RI, Ring Indicate) of the serial connector is not used for this course.
